What is a data scientist

About data scientists

Rising alongside the relatively new technology of [big data](#) is the new job title data scientist. While not tied exclusively to [big data](#) projects, the data scientist role does complement them because of the increased breadth and depth of data being examined, as compared to traditional roles.

What is a Data Scientist?

Vice president of big data products at IBM, says:

“A data scientist is somebody who is inquisitive, who can stare at data and spot trends”

“It's almost like a Renaissance individual who really wants to learn and bring change to an organization.”

Reality

Fantasy

YOUR PERSONAL "FLYING CARPET" Step into it, press a button, and off you go to market, to a friend's home, or to your job. Take off and land anywhere; no parking problems. Plug in to any electric outlet for recharging. They're working on it!

MORE POWER TO YOU!

America's independent light and power companies build for your new electric living

Tomorrow's higher standard of living will put electricity to work for you in ways still unheard of!

The time isn't too far off, the experts say, when you'll wash your dishes without soap or water—ultrasonic waves will do the job. Your beds will be made at the touch of a button. The kids' homework

will be made interesting and even exciting when they are able to dial a library book, a lecture or a classroom demonstration right into your home—with sound. (Some of this is happening already.)

To enjoy all this, you'll want a lot more electric power, and the independent electric companies of America are already building

new plants and facilities to provide it. Right now these companies are building at the rate of \$5,000,000,000 a year, and planning to double the nation's supply of electricity in less than 10 years.

America has always had the best electric power service in the world. The electric companies are resolved to keep it that way.

PART 2 SOCIAL AREAS AND CLUSTERS

33 The city of Liverpool is shown divided into five types of area in figure 2

a high status area of owner occupied houses with stable families

a rooming house area of subdivided houses providing furnished privately rented accommodation chiefly for young people

the inner council estates, mainly though not exclusively the older blocks of flats

the outer council estates, mainly houses and newer blocks of flats

Table 4 Social areas: general characteristics

	city mean (%)	social areas (city = 100)				
	1	2	3	4	5

*ratio

to neighbourhoods and works at millions of households of which approximately one million have been included in the study. The remaining two million have been excluded because they are not in the census returns.

an area of older terraced housing, mostly unfurnished privately rented houses many lacking an inside wc.

34 The key characteristics of each area are shown in table 4, expressed as percentages of the average for the city as a whole. Thus the ratio to the city mean for owner occupied households in the high status area is 236, meaning that 71% of all households in that area are owner occupiers as the average in the city as a whole is 30%.

35 The relative size of each social area is shown in table 5. The second and third are smaller than the others and the fourth has the largest population, the largest number of clusters and also the largest number of basic data areas. Furthermore, the average population size of basic data areas is larger in the fourth area and particularly small in the second. This implies that the outer council estates contain large tracts of housing which are socially homogeneous whereas the rooming house area is more sharply split up into small areas with different social characteristics.

36 The social areas are most strongly related with the pattern of housing tenure in the city in two important respects. Each area as a whole is characterised by a single type of tenure not only in the composition of its own housing stock but also in the extent to which it contains within its boundaries a large proportion of all houses in that category in the city. Thus the high status area contains over half the city's owner occupied houses and virtually all of its newer houses in that category. The rooming house and older terraced areas split the rest of the private houses between them, the furnished rented in one and the unfurnished rented and most of the remaining (mainly older) owner occupied houses in the other. And the inner and outer council areas contain between them virtually all of the city's council housing.

37 Another important feature of the system is that to a very large extent each social area is comparatively homogeneous in the make up of its housing stock. That is, all clusters and basic data areas in a given area are pretty similar in their housing composition, as is shown in table 1. No other characteristic is so strongly related with the system as a whole, since for no other does the amount of variation retained stay as high as for housing tenure.

38 The social areas are comparatively poorly related to the distribution of social classes in the city in the sense that

Table 5 Distribution of population, tenure and status by social area

		social areas					city total
		1	2	3	4	5	
population		22	9	9	33	27	100
tenure

POINT OF VIEW

Learning to code

ALEX SINGLETON

is a lecturer in geographic information science at the University of Liverpool

IN MY OPINION, a geography curriculum should require students to learn how to code, ensuring that they're equipped for a changed job market that's increasingly detached from geographic information systems (GIS) as they were originally conceived.

The ability to code relates to basic programming and database skills that enable students to manipulate large and small geographic data sets, and to analyse them in automated and transparent ways. Although it might seem odd for a geographer to want to learn programming languages, we only have to look at geography curriculums from the 1980s to realise that these skills used to be taught.

For example, it wouldn't have been unusual for an undergraduate geographer to learn how to programme a basic statistical model (for example, regression) from base principles in Fortran (a programming language popular at the time) as part of a methods course.

But during the 1990s, the popularisation of graphical user interfaces in software design enabled many statistical, spatial analysis and mapping operations to be wrapped up within visual and menu-driven interfaces, which were designed to lower the barriers of entry for users of these techniques. Gradually, much GIS teaching has transformed into learning how these

software systems operate, albeit within a framework of geographic information science (GISc) concerned with the social and ethical considerations of building representations from geographic data. Some Masters degrees in GISc still require students to code, but few undergraduate courses do so.

The good news is that it's never been more exciting to be a geographer. Huge volumes of spatial data about how the world looks and functions are being collected and disseminated. However, translating such data safely into useful information is a complex task.

During the past ten years, there has been an explosion in new platforms through which geographic data can be processed and visualised. For example, the advent of services such as Google Maps has made it easier for people to create geographical representations online.

However, both the analysis of large volumes of data and the use of new methods of representation or analysis do require some level of basic programming ability. Furthermore, many of these developments haven't been led by geographers, and there's a real danger that our skill set will be seen as superfluous to these activities in the future without some level of intervention.

Indeed, it's a sobering experience to look through the pages of job advertisements for GIS-type roles in the UK and internationally. Whereas these might once have required knowledge of a particular

software package, they increasingly look like advertisements for computer scientists, with expected skills and experience that wouldn't traditionally be part of an undergraduate geography curriculum.

Many of the problems that GIS set out to address can now be addressed with mainstream software or shared online services that are, as such, much easier to use. If I want to determine the most efficient route between two locations, a simple website query can give a response within seconds, accounting for live traffic-volume data. If I want to view the distribution of a census attribute over a given area, there are multiple free services that offer street-level mapping. Such tasks used to be far more complex, involving specialist software and technical skills.

There are now far fewer job advertisements for GIS technicians than there were ten years ago. Much traditional GIS-type analysis is now sufficiently non-technical that it requires little specialist skill, or has been automated through software services, with a subscription replacing the employment of a technician. The market has moved on.

Geographers shouldn't become computer scientists, however; we need to reassert our role in the development and critique of existing and new GIS. For example, we need to ask questions such as which type of geographic representation might be most appropriate for a given dataset. Today's geographers may be able to talk in general terms about such a question, but they need to be able to provide a more effective answer that encapsulates the technologies that are used for display. Understanding what is and isn't possible in technical terms is as important as understanding the underlying cartographic principles. Such insights will be more available to a geographer who has learnt how to code.

Within the area of GIS, technological change has accelerated at an alarming rate in the past decade and geography curriculums need to ensure that they embrace these developments. This does, however, come with challenges. Academics must ensure that they are up to date with market developments and also that there's sufficient capacity within the system to make up-skilling possible.

Prospective geography undergraduates should also consider how the university curriculums have adapted to modern market conditions and whether they offer the opportunity to learn how to code. ■

UNIVERSITY OF
LIVERPOOL

The Course . . .

- Practicals
 - Introduction to R
 - Data Manipulation in R
 - Descriptive statistics
 - Charts and graphs
 - Mapping areas and contexts
 - Visualising point patterns
 - Mapping flows
- **For a city anywhere in the world; utilize those skills acquired during this course to create a data driven profile that describes:**
 - **Some aspects of population structure**
 - **An attribute that varies over both space and time**
 - **The spatial distribution of a social outcome**

Many Thanks
